Two	CELLS OBEY THE LAWS OF CHEMISTRY	32
	The Concept of Intermediary Metabolism	38

Energy Generation by Oxidation-Reduction Reactions	39
Most Biological Oxidations Occur without Direct Participation of Oxygen	42
The Breakdown of Glucose	43
Involvement of Phosphorus and the Generation of ATP	48
Most Specific Cellular Reactions Require a Specific Enzyme	50
The Key Role of Pyruvate: Its Utilization via the Krebs Cycle	53
Oxidation of Reduced Coenzymes by Respiratory Enzymes	54
Synthesis of ATP in the Presence of Oxygen (Oxidative Phosphorylation)	56
Generation of ATP during Photosynthesis	58
Vitamins and Growth Factors	59
The Lability of Large Molecules	60
Implications of Chromatography	62
The 25-Year Loneliness of the Protein Crystallographers	62
Avery's Bombshell: Nucleic Acids Can Carry Genetic Specificity	64
The Double Helix	66
The Goal of Molecular Biology	67
Summary	68
References	69

Three **A CHEMIST'S LOOK AT THE BACTERIAL CELL** 71

Bacteria Grow under Simple, Well-Defined Conditions	71
<i>E. Coli</i> is the Best Understood Organism at the Molecular Level!	73
Even Small Cells Are Complex	80
Macromolecules Constructed by Linear Linking of Small Molecules	87
Distinction between Regular and Irregular Polymers	93
Metabolic Pathways	94
Degradation Pathways Distinct from Biosynthetic Pathways	95
The Significance of a Finite Amount of DNA	98
One-Fifth to One-Third of the Chemical Reactions in <i>E. Coli</i> Are Known	99
Summary	100
References	101

Four **THE IMPORTANCE OF WEAK CHEMICAL INTERACTIONS** 102

Definition and Some Characteristics of Chemical Bonds	103
---	-----

Chemical Bonds Are Explainable in Quantum-Mechanical Terms	105
Chemical-Bond Formation Involves a Change in the Form of Energy	106
Equilibrium between Bond Making and Breaking	107
The Concept of Free Energy	107
K_{eq} Is Exponentially Related to ΔG	108
Covalent Bonds Are Very Strong	109
Weak Bonds Have Energies between 1 and 7 kcal/mole	109
Weak Bonds Constantly Made and Broken at Physiological Temperatures	110
Enzymes Not Involved in Making (Breaking) of Weak Bonds	110
Distinction between Polar and Nonpolar Molecules	110
van der Waals Forces	112
Hydrogen Bonds	115
Some Ionic Bonds Are, in Effect, Hydrogen Bonds	118
Weak Interactions Demand Complementary Molecular Surfaces	119
H ₂ O Molecules Form Hydrogen Bonds	119
Weak Bonds between Molecules in Aqueous Solutions	121
Organic Molecules That Tend to Form Hydrogen Bonds Are Water Soluble	122
The Uniqueness of Molecular Shapes; The Concept of Selective Stickiness	122
The Advantage of ΔG 's between 2 and 5 kcal/mole	125
Weak Bonds Attach Enzymes to Substrates	126
Most Molecular Shapes Determined by Weak Bonds	126
Polymeric Molecules Are Sometimes Helical	128
Protein Structures Are Usually Irregular	130
DNA Can Form a Regular Helix	130
DNA Molecules Are Stable at Physiological Temperatures	131
Most Medium Size and Almost All Large Protein Molecules Are Aggregates of Smaller Polypeptide Chains	134
Subunits Are Economical	135
The Principle of Self-Assembly	136
Summary	138
References	139

Five COUPLED REACTIONS AND GROUP TRANSFERS 141

Food Molecules Are Thermodynamically Unstable	142
Distinction between Direction and Rate of a Reaction	143

Enzymes Lower Activation Energies	145
A Metabolic Pathway Is Characterized by a Decrease in Free Energy	145
High-Energy Bonds Hydrolyze with Large Negative ΔG 's	146
High-Energy Bonds Necessary for Biosynthetic Reactions	148
Peptide Bonds Hydrolyze Spontaneously	149
Coupling of Negative with Positive ΔG	150
Activation through Group Transfer	151
ATP Versatility in Group Transfer	152
Activation of Amino Acids by Attachment of AMP	154
Nucleic Acid Precursors Activated by Presence of $\text{P} \sim \text{P}$	155
Value of $\text{P} \sim \text{P}$ Release in Nucleic Acid Syn- thesis	156
$\text{P} \sim \text{P}$ Splits Characterize Most Biosynthetic Reactions	157
Summary	158
References	159

Six THE CONCEPT OF TEMPLATE SURFACES 160

Synthesis of Small Molecules	161
Synthesis of a Large "Small Molecule"	165
Synthesis of a Regular, Very Large Polymeric Molecule	168
A Deeper Look into Protein Structure	168
The Primary Structures of Proteins	172
Secondary Structures of Proteins May Be Sheets or Helices	174
Tertiary Structures of Proteins Are Exceedingly Irregular	175
S—S Bonds Form Spontaneously between Correct Partners	176
Enzymes Cannot Be Used to Order Amino Acids in Proteins	179
Template Interactions Are Based on Relatively Weak Bonds	180
Attraction of Opposites versus Self-Attraction	180
A Chemical Argument against the Existence of Protein Templates	181
Summary	182
References	183

Seven THE ARRANGEMENT OF GENES ON CHROMOSOMES 184

Much Remains to Be Learned about the Molecular Aspects of Chromosome Structure	185
The Genetic Cross	186
Chromosome Mapping	189

Importance of Work with Microorganisms	193
The Value of Mutagens	194
Bacterial Mutations: The Use of Growth Factors	195
Viruses Also Contain Chromosomes	198
Viruses Do Not Grow by Gradual Increase in Size	199
Viruses are Parasites at the Genetic Level	201
Bacterial Viruses (Phages) Are Often Easy to Study	201
Phages Form Plaques	203
Virus Chromosomes Are Sometimes Inserted into the Chromosomes of Their Host Cells	204
Bacterial-Chromosome Mapping by Mating	207
Bacterial Chromosomes Are Circular	209
Phages Occasionally Carry Bacterial Genes	215
Transfer of Purified Chromosome Fragments	218
Phages Also Mutate	220
Phage Crosses	222
Viral Crosses Involve Multiple Pairings	226
Summary	227
References	228

Eight **GENE STRUCTURE AND FUNCTION** 230

Recombination within Genes Allows Construction of a Gene Map	231
The Complementation Test Determines if Two Mutations Are in the Same Gene	235
Genetic Control of Protein Function	237
One Gene—One Polypeptide Chain	240
Recessive Genes Frequently Do Not Produce Functional Products	241
Genes with Related Functions Are Often Adjacent	241
Proof That Genes Control Amino Acid Sequences in Proteins	244
Colinearity of the Gene and its Polypeptide Product	245
A Mutable Site Can Exist in Several Alternative Forms	247
Single Amino Acids Are Specified by Several Adjacent Mutable Sites	249
Unique Amino Acid Sequences Are Not Required for Enzyme Activity	250
“Reverse” Mutations Sometimes Cause a Second Amino Acid Replacement	252
Summary	253
References	254

Nine **THE REPLICATION OF DNA** 255

The Gene Is (Almost Always) DNA	257
---------------------------------	-----

The Amount of Chromosomal DNA Is Constant	259
Viral Genes Are Also Nucleic Acids	259
DNA Is Usually a Double Helix	261
The Complementary Shape Immediately Suggests Self-replication	266
Base Pairing Should Permit Very Accurate Replication	268
DNA Carries All the Specificity Involved in Its Self-replication	269
Solid Evidence in Favor of DNA Strand Separation	271
Single-Stranded DNA Also Is Replicated by Base Pairing	273
Single DNA Molecules Are the Chromosomes of Viruses and <i>E. Coli</i>	275
DNA Molecules Sometimes Have a Circular Shape	276
Test Tube Replication of a Biologically Active DNA Molecule	279
Replication Must Start with an Endonuclease Cut	281
Evidence for Unique Starting Points	282
Direct Visualization of Replicating DNA	282
Chain Growth in Both 5' to 3' And 3' to 5' Directions	284
Meaning of the Small Fragments Found Near the Growing Points	287
Attachment of Daughter Polynucleotide Material to Parental Strands	287
The Rolling Circle Model	288
Opposing Rolling Circle Models	288
Single Rolling Circles	290
Repair Synthesis	292
Cells without DNA Polymerase	295
Membrane Involvement in Replication	295
Summary	296
References	298

Ten THE GENETIC ORGANIZATION OF DNA

299

Theoretically, a Very, Very Large Number of Different Sequences Can Exist	299
Mutations Are Changes in the Sequence of Base Pairs	300
Precise Statements about Some Chemical Mutagens	305
Gaps between Genes Are Relatively Short	306
Agreement of a Genetic Map with the Corresponding Distance Along a DNA Molecule	
The Average Gene Contains about 900 to 1500 Nucleotide Pairs	311
Crossing Over Is Due to Breakage and Rejoining of Intact DNA Molecules	311
Involvement of Specific Enzymes in the Recombination Process	316

Stabilization of Extended Single-Stranded Tails by a Recombination-Promoting Protein	318
Heteroduplexes	318
Recombination Is Not Always Reciprocal at the Site of Crossing Over	320
Insertions (Deletions Usually) Derive from Errors in Crossing Over	322
Hot Spots are Often Sites of Mismatching	324
The Genetic Code is Read in Groups of Three	324
Summary	327
References	328

Eleven **THE TRANSCRIPTION OF RNA
UPON DNA TEMPLATES** 330

The Central Dogma	330
Protein Synthesis in Absence of DNA	331
RNA is Chemically Very Similar to DNA	336
RNA is Usually Single-Stranded	336
Enzymatic Synthesis of RNA upon DNA Templates	337
Along Each Gene Only One DNA Strand Acts as an RNA Template	342
RNA Chains Are Not Circular	346
Synthesis of RNA Chains Occurs in a Fixed Direction	346
Construction of RNA Polymerase from Subunits	348
Recognition of Start Signals by σ	349
Chains Start with Either pppA or pppG	350
Release Factors Produce Chains of Finite Length	350
Summary	352
References	353

Twelve **INVOLVEMENT OF RNA
IN PROTEIN SYNTHESIS** 355

Amino Acids Have No Specific Affinity for RNA	355
Amino Acids Attach to RNA Templates by Means of Adapters	356
Specific Enzymes Recognize Specific Amino Acids	356
The Adapter Molecules Are Themselves RNA Molecules	358
Yeast Alanine tRNA Contains 77 Nucleotides	360
Cloverleaf Folding of tRNA Molecules	362
Crystalline tRNA	363
Addition of the Adapter Also Activates the Amino Acid	365
Peptide-Bond Formation Occurs on Ribosomes	367
Ribosome Reconstitution	370
Ribosome-Associated RNA Does Not Usually Carry Genetic Information	370
Template RNA (mRNA) Reversibly Associates with Ribosomes	371

rRNA Exists in Two Major Size Classes	371
The Function of rRNA Is Not Yet Known	372
All Three Forms of RNA Are Made on DNA Templates	372
mRNA Molecules Exist in a Large Variety of Sizes	373
Ribosomes Come Apart into Subunits during Protein Synthesis	374
Polypeptide Chain Growth Starts at the Amino Terminal End	376
Starting of All Bacterial Polypeptide Chains with N-formyl-methionine	377
Binding of the Smaller Ribosomal Subunit to Specific Points along mRNA Molecules	379
Initiation Factors	381
The Direction of mRNA Reading is 5' to 3'	383
Each Ribosome Has Two tRNA Binding Sites	383
Existence of Transfer Factors	385
Binding of AA ~ tRNA to the "A" Site Requires Transfer Factor I	386
The Peptide-Bond-Forming Enzyme is an Integral Component of the 50-S Particle	386
Peptidyl-tRNA Translocation Requires Transfer Factor II	386
Inhibition of Specific Steps in Protein Synthesis by Antibiotics	387
Polypeptide Chains Fold Up Simultaneously with Synthesis	387
Chain Release Depends upon Specific Release Factors Which Read Chain-Terminating Codons	389
Breaks in Polypeptide Chains after Chain Termination	389
An mRNA Molecule Works on Several Ribosomes Simultaneously	390
Much More Must Be Learned about Ribosomes	391
Summary	395
References	396

Thirteen THE GENETIC CODE

398

Addition of mRNA Stimulates <i>in Vitro</i> Protein Synthesis	398
Viral RNA Is mRNA	401
Specific Proteins Can Be Made in Cell-Free Systems	401
Stimulation of Amino Acid Incorporation by Synthetic mRNA	402
Poly U Codes for Polyphenylalanine	404
Mixed Copolymers Allow Additional Codon Assignments	404
Ordering Codons by tRNA Binding	406
Codon Assignment from Regular Copolymers	407
The Code Is Degenerate	410
The Wobble in the Anticodon	411
Minor tRNAs	414
AUG and GUG as Initiation Codons	415

Codons for Chain Termination	415
Ending of a Polypeptide Message with Two Successive Stop Codons	416
Nonsense versus Missense Mutations	416
Nonsense Mutations Produce Incomplete Poly- peptide Chains	419
Reading Mistakes Can Occur in Cell-Free Protein Synthesis	420
Suppressor Genes Upset the Reading of the Genetic Code	420
Specific Codons Are Misread by Specific Suppressor Genes	423
Nonsense Suppression Involves Mutant tRNAs	424
tRNA-Mediated Missense Suppression	426
Ribosomal Mutations Also Affect the Reading Accuracy	427
Streptomycin Causes Misreading	427
Suppressor Genes Also Misread Good Genes	430
The Code Is Largely, If Not Entirely, Universal	431
Summary	431
References	433

Fourteen **REGULATION OF PROTEIN
SYNTHESIS AND FUNCTION** 435

All Proteins Are Not Produced in the Same Numbers	435
Variations in the Amounts of Different <i>E. Coli</i> Proteins	436
Relation between Amount of and Need for Specific Proteins	438
Variation in Protein Amount Can Reflect the Number of Specific mRNA Molecules	439
Repressors Control the Rate of Much mRNA Synthesis	440
Repressors Are Proteins	441
Repressors Act by Binding to DNA	441
Corepressors and Inducers Determine the Functional State of Repressors	442
Repressors Can Control More Than One Protein	443
Absence of an Operator Leads to Constitutive Synthesis	445
mRNA Synthesis Starts near the Promoter	449
Unequal Production of Proteins Coded by a Single mRNA Molecule	450
Bacterial mRNA Is Often Metabolically Unstable	451
Proteins Not Under Direct Environmental Control	453
Repressor Synthesis is Usually under Promoter Not Operator Control	454
The Question of Positive Control	456
Specific σ Factors May Be Used to Turn On Large Blocks of Unrelated Genes	458
The Existence of Glucose-Sensitive Operons	458

	Glucose Catabolism Affects the Cyclic AMP Level	459
	Regulation of Protein Function by Feedback Inhibition	460
	Summary	464

	A Single Promoter for all Late λ Genes	487
	A Single Operon for the Very Small DNA Phages	490
	Viral RNA Self-replication: Requirements for a New Viral Specific Enzyme	491
	RNA Phages are Very, Very Simple	493
	Initial Binding of Ribosomes at Two Independent Sites	494
	Polarity Gradients	494
	Unequal Production of the Three R17 Proteins	496
	Test Tube Synthesis of Biologically Active Q β RNA	497
	Elucidation of the Complete Nucleotide Sequences of Q β and R17 May Soon Occur	498
	Satellite RNA Codes Only for Coat-Protein Molecules	501
	The Smallest Known Viruses Are Almost at the Lower Limit for a Virus	501
	A Lower Size Limit Exists for Dividing Cells	502
	Summary	503
	References	504
Sixteen	EMBRYOLOGY AT THE MOLECULAR LEVEL	506
	Amount of DNA per Cell Increases about Eight Hundredfold from <i>E. Coli</i> to Mammals	507

Concentration on Organisms with Easily Observable Cleavage Divisions	509
The Heart of Embryology Is the Problem of Cell Differentiation	509
Differentiation Is Often Irreversible	512
Differentiation Usually Is Not Due to Chromosome Gain or Loss	512
Multicellular Organisms Must Have Devices to Control When Genes Act	513
Necessity of Finding Simple Model Systems for Studying Differentiation	514
Bacterial Sporulation as the Simplest of All Model Systems	515
The Difference between Eucaryotic and Procaryotic Cells	518
There Are Now Many Reasons to Work on Organisms Like Yeast	519
Mitochondria as Defective Procaryotic Symbionts	520
Reversible States of the Slime Mold Cell	521
Growth of Higher Animal Cells in Tissue Culture	523
Cloning of Highly Differentiated Cells	524
Division of the Cell Cycle into M, G ₁ , S, and G ₂ Phases	526
Transcription as a Measure of Biological Time	528
The Eucaryotic Chromosome	529
Replication of DNA Starts at a Number of Different Sites along a Given Chromosome	533
Active (Euchromatin) versus Inactive (Heterochromatin) Chromosomal Regions	533
Even the Smallest Bands (Loops) Must Contain Many, Many Genes	537
Highly Repetitive DNA Sequences	540
Variation in DNA Amounts between Closely Related Species	541
The Nucleolar Location of rRNA synthesis	543
The Very Large Forms of Much Newly Made RNA in Higher Cells	544
Most RNA Never Leaves the Nucleus	545
Polyribosome Lifetimes in Rapidly Dividing Cells	546
Stable mRNA Molecules Exist in Nondividing Differentiated Cells	547
Selective Multiplication of the rRNA Genes within Oocytes	547
Differentiated Somatic Cells with Extrachromosomal Genes	549
Differentiation Is Usually Not Irreversible at the Nuclear Level	549
Irreversible Cytoplasmic Differentiation Concomitant with Loss of Ability to Divide	551
Revival of Dormant Nuclei through Fusion with More Active Cells	551
Positive Control of Gene Function	553
Preformed mRNA on the Way to Gastrulation	555
Further Deciphering of the Eucaryotic Chromosome	556

Summary 556
References 558

Seventeen	THE PROBLEM OF ANTIBODY SYNTHESIS	561
	Antigens Are Agents Which Stimulate Antibody Synthesis	561
	Antibodies Are Always Proteins	564
	Construction of the γ G Antibody Molecule from Two Light and Two Heavy Chains	565
	Antibody Specificity Resides in Amino Acid Sequences	567
	Myeloma Proteins as Models for Single Antibodies	569
	Bence-Jones Proteins Are Specific Light Chains	570
	Light and Heavy Chains Have Constant and Variable Portions	570
	Heavy-Chain Origin through Repetitive Duplication of a Primitive Antibody Gene	573
	Light and Heavy Chains Both Influence the Specificity of Antibodies	575
	Plasma Cell Site of Antibody Synthesis	575
	A Given Plasma Cell Usually Produces One Type of Antibody Molecule	576
	Second Injection of Antigen Increases the Number of Antibody-Producing Cells	579
	Antibody-Producing Cells Need Not Contain Antigens	579
